

Series resistors are connected to the foil paths between the transmitter and the first receiver if that receiver is on another chip. If the transmitter and the first receiver are on the same chip the series resistor is located after the first receiver. The foil from the transmitter is always connected to the left side of the resistor when the resistor is placed with the two diamonds on top and the solid octagon below. The right side of the resistor has foil running to the receiver in that artwork listing.
